DECLARATION

I hereby certify that the work which is being presented in the project report entitled “**Digital Forgetting: Is Selective Memory Essential for Artificial Intelligence?**” in partial fulfilment of requirement for the award of the degree of Bachelor of Engineering (Computer Science and Engineering) submitted in the department of Computer Science and Engineering at Chitkara University Institute of Engineering and Technology, Chitkara University, Punjab, India, is an authentic record of my own work carried out under the supervision of **Dr. Ajay Kumar**. The matter presented in this project report has not been submitted in any other university/institute for the award of any degree.

Place: Rajpura

Date: 14/05/2026

Date: 14/05/2026

Ansh Goyal , Abhijeet Sharma)

(2210991274 , 2210991313

2210991294 , 2210991150)

This is to certify that the above statement made by the candidate is correct to the best of my knowledge and belief.

Dr. Ajay kumar

Associate Professor

Department of Computer Science and Engineering

Chitkara University Institute of Engineering and Technology,

Chitkara University, Punjab, India

ACKNOWLEDGEMENT

We would like to express our sincere gratitude to all those who have contributed to the successful completion of this project report on " Digital Forgetting: Is Selective Memory Essential for Artificial Intelligence?".

We are deeply thankful to our mentor Dr. Ajay Kumar, Associate Professor, for their invaluable guidance, constant encouragement, and constructive feedback throughout the course of this project. Their expertise and insights have been instrumental in shaping the direction and quality of this work. We extend our heartfelt thanks to the Department of Computer Science and Engineering, Chitkara University Institute of Engineering and Technology, Chitkara University, Punjab, for providing us with the necessary resources and a conducive environment to carry out this research.

We are also grateful to our peers and colleagues for their support, discussions, and motivation during the development of this project. Finally, we would like to acknowledge the researchers and authors whose published works and datasets have provided a strong foundation for our study. The Kaggle "Predict Online Course Engagement Dataset" used in our experiments is gratefully acknowledged.

1. Introduction

Artificial Intelligence is one of the most important technologies in today's digital world. It is used in many domains such as healthcare, finance, transportation, e-commerce, and education. Systems like recommendation engines, virtual assistants, fraud detection systems, and autonomous vehicles depend heavily on AI to process large amounts of data and make intelligent decisions.

Most AI systems are built on the assumption that more data leads to better performance. While this is true initially, continuous accumulation of data creates several long-term problems. As data grows, it increases storage requirements, slows down processing, and introduces outdated or irrelevant information into the system.

Inspired by this, our research introduces the concept of digital forgetting, where AI systems intelligently remove unnecessary or outdated data while retaining valuable information.

This helps AI systems become more efficient, adaptive, and closer to human-like intelligence.

The principal driver of the AI systems is big data. They continuously accumulate and analyze information on users, sensors and electronic platforms to augment their learning and performance.

The systems traditionally are constructed based on the understanding that the more data, the greater the accuracy and the intelligence. This is a good way in the early stages but there are two issues with time as the data continue to accumulate. As the size of the data gatherings grows, they take up more storage capacity and computation opportunities and might slug presence in system execution and escalate operational costs. Moreover, not all the data stored comes in handy.

2. Problem Statement

Modern AI systems face several major challenges due to uncontrolled data storage.

First, there is data overload. AI systems continuously collect data from users, sensors, and applications. This leads to exponential growth in stored data, making systems difficult to manage.

Second, computational complexity increases. Larger datasets require more processing power, which slows down training and prediction.

Third, outdated data remains in the system. Old data may not represent current trends and can negatively affect predictions.

Fourth, there are privacy concerns. Storing personal data indefinitely can violate regulations such as GDPR, which includes the "right to be forgotten."

3. Software Interaction

The ForgetAI system demonstrates how digital forgetting works in practice. When a user inputs data (such as text or messages), the system stores it in a database along with metadata like importance, usage, and timestamp. The system then processes this data using a mathematical model. It calculates a score based on:

- Importance of the data
- Frequency of usage
- Time elapsed (decay factor)

Based on this score:

- High-score data is retained
- Low-score data is removed

The results are displayed on a dashboard where users can see:

- Stored data
- Forgotten data
- Memory efficiency
- Graphs and comparisons

=>This creates a clear comparison between:

Normal AI (stores everything)

ForgetAI (filters data intelligently)

4. Objectives:

The main objectives of this research are:

- To introduce the concept of digital forgetting in AI systems
- To reduce memory overload and improve system efficiency
- To remove outdated and irrelevant data automatically
- To improve decision-making by retaining only useful information
- To enhance privacy and comply with data protection laws
- To develop AI systems that behave more like human memory

5. Data Flow Diagram:

- **Sign In/Sign Up:**

User inputs credentials (username/email and password) in the sign-in form .Server verifies credentials against the database.

- **Authentication:**

Authenticated user makes a request to access protected routes or perform actions (e.g., add new property, view user profile).

- **User Profile:**

Authenticated user navigates to the profile page. React component sends a request to the server to fetch user data using the authentication token.

- **Add New Property:**

Authenticated user fills out the property details form (e.g., address, price, description, images). Server validates the token and inserts the new property information into the database.

- **Search Property:**

User interacts with the search bar or filters to specify search criteria (e.g., location, price range, property type). Server sends the list of matching properties back to the client.

- **Manage and Browse Property:**

Authenticated user navigates to the property management or browsing section.

FAQ

How ForgetAI Works

- 1 Memory Encoding**
Stores data with importance and usage.
- 2 Scoring Model**
Applies exponential decay over time.
- 3 Intelligent Forgetting**
Removes low-value memories dynamically.
- 4 Optimization**
Improves efficiency while keeping accuracy.

Forgets intelligently

7. Future Scope

In the Future, it is possible to make digital forgetting smarter and more automatic.

- **AI SYSTEMS** can learn by themselves what to retain and what to forget, without manual control. This will make the system quicker and efficient. Science is also trying to develop more effective methods of deleting data without any performance loss so that the system remains accurate even when it forgets.
- **AS DATA PRIVACY RULES** are getting tighter, digital forgetting will also aid AI systems in preserving user data and adhering to legal requirements. In simple terms, improvement in the future is going to consist of
 - **SMARTER** Artificial Intelligence that makes decisions on what to forget automatically.
 - **LEARNING**-based systems that enhance forgetting with time. Application in the real world of forgetting using digital.

8. Conclusion

Digital forgetting is an effective and essential concept of the development of modern AI systems, as it is based on the priority, filtration, and discarding of information inherent in human memory with time. Similar to humans dropping unnecessary or old information to ensure they can have more significant and better experiences, an AI system can enjoy the benefit of selective deletion of redundant information, low-value information, or outdated information. This allows not only to increase the computational efficiency but also to reduce storage overhead dramatically to allow systems to scale and not be overwhelmed by irrelevant information. Additionally, digital forgetting is also important in improving user privacy and data security.

To sum up, digital forgetting is not just a limitation but also a strategic asset. It is a move towards storing data to smart data, and a move towards more efficient, ethical, and intelligent AI systems. As the research of this field advances, in the construction of scalable, human-like artificial intelligence systems, the idea of digital forgetting will form the backbone of an artificial intelligence system that is capable of operating in the future
